1.1.4 Function Documentation

1.1.4.1 int Mat_CalcSingleSubscript (int *rank*, int * *dims*, int * *subs*)

Calculates a single linear subscript (0-relative) given a 1-relative subscript for each dimension. The calculation uses the formula below where *index* is the linear index, *s* is an array of length *RANK* where each element is the subscript for the corresponding dimension, *D* is an array whose elements are the dimensions of the variable.

$$index = \sum_{k=0}^{RANK-1} [(s_k - 1) \prod_{l=0}^k D_l]$$

Parameters

rank Rank of the variable

dims dimensions of the variable

subs Dimension subscripts

Returns

Single (linear) subscript

1.1.4.2 int* Mat_CalcSubscripts (int *rank*, int * *dims*, int *index*)

Calculates 1-relative subscripts for each dimension given a 0-relative linear index. Subscripts are calculated as follows where *s* is the array of dimension subscripts, *D* is the array of dimensions, and *index* is the linear index.

$$s_k = \lfloor \frac{1}{D_k} \prod_{l=0}^k D_l \rfloor + 1$$

$$L = index - \sum_{l=k}^{RANK-1} s_l \prod_{m=0}^l D_m$$

Parameters

rank Rank of the variable

dims dimensions of the variable

index linear index

Returns

Array of dimension subscripts

1.1.4.3 int Mat_Close (mat_t * *mat*)

1.1.4.10 `matvar_t* Mat_VarCreate(const char * name, int class_type, int data_type, int rank, int * dims, void * data, int opt)`

Creates a MAT variable that can be written to a Matlab MAT file with the given name, data type, dimensions and data. Rank should always be 2 or more. i.e. Scalar values would have rank=2 and `dims[2] = {1,1}`. Data type is one of the MAT_T types. MAT adds MAT_T_STRUCT and MAT_T_CELL to create Structures and Cell Arrays respectively. For MAT_T_STRUCT, data should be a NULL terminated array of `matvar_t` * variables (i.e. for a 3x2 structure with 10 fields, there should be 61 `matvar_t` * variables where the last one is NULL). For cell arrays, the NULL termination isn't necessary. So to create a cell array of size 3x2, data would be the address of an array of 6 `matvar_t` * variables.

EXAMPLE: To create a struct of size 3x2 with 3 fields:

```
int rank=2, dims[2] = {3,2}, nfields = 3;
matvar_t **vars;

vars = malloc((3*2*nfields+1)*sizeof(matvar_t *));
vars[0] = Mat_VarCreate(...);
:
vars[3*2*nfields-1] = Mat_VarCreate(...);
vars[3*2*nfields] = NULL;
```

EXAMPLE: To create a cell array of size 3x2:

```
int rank=2, dims[2] = {3,2};
matvar_t **vars;

vars = malloc(3*2*sizeof(matvar_t *));
vars[0] = Mat_VarCreate(...);
:
vars[5] = Mat_VarCreate(...);
```

Parameters

name Name of the variable to create

class_type class type of the variable in Matlab(one of the mx Classes)

data_type data type of the variable (one of the MAT_T_ Types)

rank Rank of the variable

dims array of dimensions of the variable of size rank

data pointer to the data

opt 0, or bitwise or of the following options:

- MEM_CONSERVE to just use the pointer to the data and not copy the data itself. Note that the pointer should not be freed until you are done with the mat variable. The `Mat_VarFree` function will NOT free data that was created with MEM_CONSERVE, so free it yourself.
- MAT_F_COMPLEX to specify that the data is complex. The data variable should be a contiguous piece of memory with the real part written first and the imaginary second
- MAT_F_GLOBAL to assign the variable as a global variable
- MAT_F_LOGICAL to specify that it is a logical variable

Returns

A MAT variable that can be written to a file or otherwise used

Provides a clean function for duplicating a [matvar_t](#) structure.

Parameters

in pointer to the [matvar_t](#) structure to be duplicated

opt 0 does a shallow duplicate and only assigns the data pointer to the duplicated array. 1 will do a deep duplicate and actually duplicate the contents of the data. Warning: If you do a shallow copy and free both structures, the data will be freed twice and memory will be corrupted. This may be fixed in a later release.

1.1.4.21 `matvar_t* Mat_VarGetStructsLinear (matvar_t * matvar, int start, int stride, int edge, int copy_fields)`

Finds structures of a structure array given a single (linear) start, stride, and edge. The structures are placed in a new structure array. If `copy_fields` is non-zero, the indexed structures are copied and should be freed, but if `copy_fields` is zero, the indexed structures are pointers to the original, but should still be freed since the `mem_conserve` flag is set so that the structures are not freed. MAT File version must be 5.

Parameters

matvar Structure matlab variable

start starting index

stride stride

edge Number of structures to get

copy_fields 1 to copy the fields, 0 to just set pointers to them. If 0 is used, the fields should not be freed themselves.

Returns
